**Authorship statement:**

Shinji Chiba collected and analyzed data, and wrote the paper.

Yutaka Nakamura designed research, performed research, and wrote the paper.

Tomoki Mizuno, Kazuyuki Abe, and Yosuke Horii performed research and collected data.

Hiromi Nagashima and Nobuhito Sasaki designed study and collected data.

Hiroyuki Kanno, Tatsuo Tanita, and Kohei Yamauchi analyzed data and wrote the paper.

**Disclosure statement:**

All authors state potential conflict of interest do not exist.

## Abstract

*Background* Several gene variants are associated with a response to an inhaled corticosteroids (ICSs) treatment in patients with bronchial asthma. A variant of the *glucocorticoid-induced transcript 1 (GLCC1)* genes has previously been associated with decreased lung function improvement upon treatment with inhaled corticosteroids in patients with bronchial asthma. Another report has also demonstrated that this genetic biomarker did not influence the change in flow volume in one second. However, no studies have considered the treatment content and the *GLCC1* variants. We were able to determine the relationship between the pulmonary function and clinical features and the variant of the *GLCC1* in Japanese asthmatic patients receiving long-term ICS treatment.

*Materials and Methods* In this study, 386 patients with bronchial asthma, who were receiving ICS and living in Japan, were recruited, genotyped, and underwent pulmonary function tests. To identify the *GLCC1* protein expression cells, endobronchial biopsy specimens were examined.

*Results* We found that the pulmonary function was not significantly different in the TT and GG homozygotes compared to the wild types. There are significant differences in the amount of risk when increasing the treatment steps for asthma between

1  
2  
3  
4  
5  
6 homozygotes and others. GLCCI1-positive cells were localized to the bronchial  
7  
8  
9 epithelial cells. The amount of GLCCI1 that cultured epithelial cells harboring *GLCCII*  
10  
11  
12 variants produced was less than the *GLCCII* wild type in the presence of a  
13  
14  
15 corticosteroid.

16  
17  
18 *Conclusions* A worsening of pulmonary function might be prevented due to other  
19  
20  
21 recently used medications which may have a positive impact on it.

## 55 **Introduction**

56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 Bronchial asthma is a disorder of the conducting airways that leads to variable airflow  
7  
8  
9 obstructions in association with airway hyperresponsiveness and a local accumulation  
10  
11  
12 of inflammatory cells, particularly eosinophils, mast cells, and T lymphocytes (1).  
13  
14  
15 Inhaled corticosteroids (ICSs) are the primary medication used in the treatment of  
16  
17  
18 bronchial asthma based on the efficacy of a strong anti-allergic agent on the  
19  
20  
21 inflammatory cells and induced-mediators (2-3). Although most asthmatic patients show  
22  
23  
24 a beneficial response to ICS, the intraindividual variability in the level of treatment  
25  
26  
27 response is large (4). There is accumulating evidence that this variability is partly  
28  
29  
30 caused by intraindividual genetic differences (5-6). Recently, Tantisira et al. identified a  
31  
32  
33 genetic variation in *glucocorticoid-induced transcript 1 genes (GLCCII)* and *T* genes on  
34  
35  
36 chromosome 7Q21.3 to be associated with a decreased lung function in those who have  
37  
38  
39 been treated with ICS (7-8). However, Hosking et al. demonstrated that they could not  
40  
41  
42 replicate the results of Tantisira et al. in post hoc analyses of seven clinical trials  
43  
44  
45 including 1924 adolescents and adults with asthma (9). In northern European  
46  
47  
48 populations of asthmatic children and young adults, *GLCCII* genotype rs37972 has  
49  
50  
51 been demonstrated to not be associated with an ICS efficacy decrease in lung function  
52  
53  
54 and asthma symptom scores (10). Recently our prospective studies have demonstrated  
55  
56  
57 that *STAT4* TT of rs925847 and *IL13* AA of rs20541 were potential genomic biomarkers  
58  
59  
60

1  
2  
3  
4  
5  
6 that predict a lower pulmonary function. Administration of high-dose ICS to asthmatic  
7  
8  
9 patients with genetic variants of *STAT4* did not respond to it, whereas the genetic  
10  
11  
12 variants of *IL13* AA might avoid the advancing of airway remodeling (11-12). Thus,  
13  
14  
15 increased FEV1 or recovered airway remodeling were dependent on the genetic  
16  
17  
18 background and treatment content. In the current study, we aimed to assess whether  
19  
20  
21 variants in the *GLCCI1* rs37972 and rs37973 genotypes were associated with  
22  
23  
24 relationships between lung function and treatment in Japanese adults receiving ICS  
25  
26  
27 treatment, and to identify *GLCCI1* positive cells in the bronchial airways.  
28  
29  
30  
31

## 32 **Materials and Methods**

### 33 **Study subjects**

34  
35  
36 All study subjects were recruited from the Iwate Medical University Hospital. Patients  
37  
38  
39 aged  $\geq 18$  years were eligible if they had a diagnosis of asthma as defined by the  
40  
41  
42 American Thoracic Society criteria for  $\geq 5$  years and were using ICS at a stable low-mid  
43  
44  
45 dose for  $\geq 1$  year before screening. Well-controlled asthmatic patients who had no other  
46  
47  
48 medical disorders, who had smoked less than 10-pack-years, and who had not been  
49  
50  
51 exposed to environmental hazards were considered for the study. This study was  
52  
53  
54  
55 approved by the Iwate Medical University Hospital Ethics Committee (H20-119) and  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 registered with Clinical Trials (JMA-IIA00045 remodeling-ICS). Prospective patients  
7  
8  
9 were notified of our desire to include them in our study, and were asked whether they  
10  
11 would be willing to participate. Upon acceptance, the subjects provided written  
12  
13 informed consent according to the ethical protocols of our institution. Subjects were  
14  
15 assessed for age, sex, asthma duration, smoking history, eosinophil counts, serum IgE  
16  
17 concentration, and spirometry. DNA was isolated from lymphocytes using standard  
18  
19 procedures. Subjects were genotyped for rs37972 and rs37973 using a 7500 Fast  
20  
21 Real-Time PCR System (Life Technologies Japan, Tokyo, Japan) to evaluate the  
22  
23 relationship between genotype and pulmonary function and asthma treatment steps.  
24  
25  
26 Treatment steps based on GINA's *Pocket Guide for Asthma Management and*  
27  
28 *Prevention –A Pocket Guide for Physicians and Nurses Update 2015*, were used as  
29  
30  
31  
32  
33  
34  
35 follows: step 2 - use of low dose controller medication plus as-needed reliever  
36  
37  
38 medication; step 3 - use of one or two controllers plus as-needed reliever medication;  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
step 4 - use of two or more controllers plus as-needed reliever medication and step 5 -  
use of higher level care and/or add-on treatment. This was determined when a sustained  
treatment step was achieved and maintained for at least 6 months and the treatment  
could not be successfully reduced further. Spirometry was performed and airway  
methacholine responsiveness was measured using an Astograph (Jupiter 21, CHEST,

1  
2  
3  
4  
5  
6 Tokyo, Japan) according to the method described by Takishima et al. (13).  
7  
8  
9

### 10 11 **Fibreoptic bronchoscopy and specimen handling**

12  
13  
14 Asthmatic patients underwent fibreoptic bronchoscopic examinations during ICS  
15  
16 treatment and then paused the use of ICS for two weeks. **Asthmatic bronchial tissues**  
17  
18 **were obtained from: i) five asthmatic patients harboring CC (wt) of rs37972 and AA**  
19  
20 **(wt) of rs37973; ii) five asthmatic patients harboring TT (homozygous) of rs37972 and**  
21  
22 **AA (wt) of rs37973; and iii) five asthmatic patients harboring CC (wt) of rs37972 and**  
23  
24 **GG (homozygous) of rs37973.** Asthmatic bronchial biopsies were performed by  
25  
26 inserting a flexible fibreoptic bronchoscope (BF-Q290; Olympus Optical Co Ltd, Tokyo,  
27  
28 Japan) under local anaesthesia as previously described in detail (14). ~~Bronchial-~~  
29  
30 ~~epithelial cells were obtained using a standard sterile single sheathed nylon cytology-~~  
31  
32 ~~brush (Olympus). Cells were harvested into 5 mL sterile PBS after each brushing. Five~~  
33  
34  
35 biopsies were taken using forceps (Olympus) in the segmental bronchi of the right lobe  
36  
37  
38 and in the bifurcations of the right bronchi. Biopsied specimens were fixed in 4%  
39  
40  
41 paraformaldehyde, immersed in sucrose, embedded in OCT compound, and then  
42  
43

Immunolocalization of GLCCI1 in the bronchial tissues was evaluated by using an

1  
2  
3  
4  
5  
6 antibody against GLCCI1 (Atlas Antibodies AB, Stockholm, Sweden). All of the  
7  
8  
9 samples were then incubated with an Alexa Fluor 488-conjugated secondary antibody  
10  
11  
12 (Life Technologies) and imaged using a confocal laser-scanning microscope (C1si;  
13  
14 Nikon, Tokyo, Japan).

### 20 **Immunoblotting analysis of GLCCI1**

21  
22  
23 To confirm whether the homozygous for *GLCCI1* patients expressed decreased protein  
24  
25  
26 levels in the bronchial epithelial cells, which had been indicated in the  
27  
28  
29 immunohistochemistry, we performed a immunoblotting analysis. Normal human  
30  
31  
32 bronchial epithelial cells were purchased from Takara (Tokyo, Japan) and maintained in  
33  
34  
35 an EGM-2-MV BulletKit (Takara) according to the manufacturer's instructions.

36  
37  
38 **Asthmatic bronchial epithelial cells were obtained using a standard sterile single**  
39  
40  
41 **sheathed nylon cytology brush (Olympus). Cells were harvested into 5 mL sterile PBS**  
42  
43  
44 **after each brushing, as previously described (15). Asthmatic bronchial epithelial cells**  
45  
46  
47 **were collected before bronchial biopsies on the opposite site of the lung.** The epithelial  
48  
49  
50 cells from normal controls, and those derived from asthmatic patients were plated at a  
51  
52  
53 density of  $1 \times 10^5$ / 10-cm dish. When the cultures were subconfluent, the culture medium  
54  
55  
56 was removed and the cells were washed twice with and incubated for 24 h in a  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 serum-free medium, followed by treatment with fluticasone propionate or budesonide  
7  
8  
9 (R&D Systems) at different concentrations and for various times. Cultured bronchial  
10  
11  
12 epithelial cells were collected and lysed in TNE buffer as previously described (16).  
13  
14  
15 Twenty micrograms of protein were resolved using 10% SDS-PAGE and transferred  
16  
17  
18 onto a polyvinylidene difluoride membrane (Bio-Rad, CA, USA). Each membrane was  
19  
20  
21 then incubated with anti-human GLCCI1 (GeneTex, Hsinchu, Taiwan) and GAPDH  
22  
23  
24 (GeneTex) antibody. **Three separated experiments from each donor were done.**  
25  
26  
27  
28

### 29 **Statistical analysis**

30  
31  
32 Statistical analyses were performed using JMP version 11 (SAS Institute Inc., Tokyo,  
33  
34  
35 Japan). All data were expressed as the mean  $\pm$  standard error of the mean. Comparison  
36  
37  
38 of the patients' characteristics between the three groups were performed using one-way  
39  
40  
41 ANOVA. Differences in genotype between treatment steps 2-4 and 5 were tested using a  
42  
43  
44 chi-square test or two-tailed Fisher's test when the number of expected cases was small.  
45  
46  
47 Genetic risks were assessed by calculating odds ratios (OR) with 95% confidence  
48  
49  
50 intervals (95% CI). Comparisons of the levels of immunoblotting intensity between the  
51  
52  
53 four or five groups were performed using a two-tailed one-way ANOVA. *P* values <  
54  
55  
56 0.05 were considered significant. *Post hoc* multiple comparisons were performed using  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 the Tukey-Kramer test for differences among all groups.  
7  
8  
9

## 10 11 **Results**

12  
13 Of 405 asthmatic patients screened, 390 of the rs37972 and 398 of the rs37973 patients  
14  
15 were successfully genotyped ( $\geq 94\%$ ). We identified 132, 172, and 86 subjects that had  
16  
17 CC wild type, CT heterozygotes, and TT homozygotes, respectively, for rs37972 (Table  
18  
19 1). We also identified 122, 184, and 92 subjects that had AA wild type, AG  
20  
21 heterozygotes, and GG homozygotes, respectively for rs37973 (Table 2). There were no  
22  
23 significant differences in age at study enrolment, sex, eosinophil count status, serum IgE  
24  
25 concentration, and pulmonary function among the three groups. **There was no trend**  
26  
27 **toward higher IgE level with genotype (Jonckheere-Terpstra test).** TT of rs37972 and  
28  
29 GG of rs37973 were associated with a higher number of asthma treatment steps (Table  
30  
31 3).

## 46 **Immunohistochemistry of GLCCI1 expression in the bronchial airways of** 47 48 **asthmatic patients**

49  
50 To confirm whether asthmatic patients expressed GLCCI1 protein in the airways, we  
51  
52 performed an immunohistochemistry of the bronchial tissues, which were derived from  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 asthmatic patients who were using ICS and temporarily stopped for two weeks. The  
7  
8  
9 GLCCI1 positive cells were localized to the epithelial cells. As shown in Figure 1,  
10  
11  
12 GLCCI1-positive cells were detected in the bronchial epithelial cells of asthmatic  
13  
14 patients harboring both *wt* of *GLCCI1* who were using ICS (A), whereas, they were **not**  
15  
16 identified as GLCCI1-positive cells in the airways of the asthmatic patients after they  
17  
18 had stopped using ICS (B). The intensity of the staining of the epithelial cells were not  
19  
20  
21 significant between genotypes (data not shown).  
22

### 29 **Influence of fluticasone and budesonide on GLCCI1 expression in bronchial** 30 31 **epithelial cells**

32  
33  
34 Having shown the increased protein levels of GLCCI1 protein in the bronchial epithelial  
35  
36 cells of the bronchial tissues derived from asthmatic patients using an ICS treatment, we  
37  
38 next evaluated the expression of GLCCI1 on cultured human bronchial epithelial cells  
39  
40  
41 in the presence of fluticasone indicated concentrations for 24 h. GLCCI1 protein  
42  
43  
44 expression by fluticasone was concentration-dependent until a peak was reached at 1  
45  
46  
47  $\mu\text{M}$  for 24 h in normal human bronchial epithelial cells (A). Time-course experiments  
48  
49  
50 performed with 1  $\mu\text{M}$  fluticasone showed no significant induction of GLCCI1 within 12  
51  
52  
53 h (B). These concentrations and time-course experiments were similar to the results that  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 were derived from budesonide experiments (data not shown).  
7  
8  
9

### 10 11 **Impact of fluticasone and budesonide on bronchial epithelial cells harboring** 12 13 **genetic variants** 14 15

16  
17 We next evaluated the differences of expression of *GLCCI1* in the bronchial epithelial  
18  
19 cells derived from healthy control subjects with both wild type of rs37972 and rs37973  
20  
21 and from asthmatic patients in the presence of 1  $\mu$ M fluticasone or budesonide for 24 h.  
22  
23  
24 There were no significant differences among the four groups when bronchial epithelial  
25  
26 cells were cultured without fluticasone (Figure 3A). Fluticasone treatment for 24 h led  
27  
28 to an increase in the expression of *GLCCI1* proteins in the epithelial cells derived from  
29  
30 the healthy control and wt asthmatic groups compared to the TT of rs37972 and GG of  
31  
32 rs37973 groups (Figure 3B). Budesonide also increased the expression of *GLCCI1*  
33  
34 protein in the healthy control and asthmatic *wt* groups compared to the TT of rs37972  
35  
36 and GG of rs37973 groups (Figure 3C).  
37

### 49 **Discussion** 50 51

52  
53 In this study, we investigated the role of the genetic variants of *GLCCI1*, TT and GG  
54  
55 homozygotes, of asthmatic patients in clinical characteristics. Several new findings have  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 emerged from this study. First, we have demonstrated that Japanese asthmatic patients  
7  
8 following an ICS treatment and having the *GLCC11* rs37972 TT and rs37973 GG  
9  
10 genotypes was not significantly associated with a reduced pulmonary function. Second,  
11  
12 we have shown that transcription factor GLCC11 is increased in the airway epithelium  
13  
14 after ICS treatment. Third, the analysis revealed a significant association between the  
15  
16 genotype of TT and GG of *GLCC11*, and the asthmatic treatment steps used with the  
17  
18 Japanese population, showing an OR of 2.78 and 2.28, respectively. **The two GLCC11**  
19  
20 **variants have been shown to have a complete linkage disequilibrium ( $r^2=0.99$ ) in**  
21  
22 **Caucasian, and this association might reflect these data.** Finally, we have observed that  
23  
24 fibroblasts harboring the genetic variants of *GLCC11* have less potential to express  
25  
26 transcription factor GLCC11 after stimulation with fluticasone or budesonide. **To date,**  
27  
28 **little is known about the function of the GLCC11 protein and the *GLCC11* gene.**

55  
56  
57  
58  
59  
60  
GLCC11 had previously been described as a thymocytespecific transcript that is rapidly  
up-regulated in response to a dexamethasone treatment (17) and represents an early  
response in steroid-regulated thymocyte apoptosis (18). Apoptosis is a key mechanism  
through which glucocorticoids resolve lymphocytic and eosinophilic inflammation in  
asthma. Therefore, decreased GLCC11 expression, as a result of the presence of rs37972  
and rs37973, may reduce inflammatory-cell apoptosis, thus leading to a diminished

1  
2  
3  
4  
5  
6 clinical response to inhaled glucocorticoids. It is plausible that the bronchial biopsy  
7  
8  
9 specimens exhibited no *GLCCI1*-positive hemocytes, which had been induced during  
10  
11  
12 apoptosis by glucocorticoid inhalation. Previous data reports a significant association  
13  
14  
15 between the *GLCCI1* variant and the response to glucocorticoid therapy in patients with  
16  
17  
18 asthma (7). A study of Japanese patients showed that *GLCCI1* rs37973 contributed to  
19  
20  
21 the annual decline in FEV1 of 30 mL/ yr. or greater, in those receiving long-term ICS  
22  
23  
24 treatment (4). The role of the *GLCCI1* gene minor allele has been examined in patients  
25  
26  
27 with other chronic inflammatory diseases, rheumatoid arthritis (19), graft-versus-host  
28  
29  
30 disease (GVHD) (20), and nephrotic syndrome (21). In terms of sensitivity to GC,  
31  
32  
33 genetic variants might be associated with the response to GC therapy in male patients  
34  
35  
36 with RA, whereas rs37972 SNP-positive donors and recipients neither increased nor  
37  
38  
39 were more likely to have steroid-refractory GVHD. Also, the *GLCCI1* SNP was not  
40  
41  
42 associated with steroid sensitivity in pediatric patients with nephrotic syndrome. One  
43  
44  
45 explanation for these differences may depend on how *GLCCI1* is expressed in the  
46  
47  
48 involved tissues. Tantisira *et al.* (7) have demonstrated the relative high level of  
49  
50  
51 expression of *GLCCI1* mRNA in the lungs. Little data is known about the *GLCCI1*  
52  
53  
54 protein expression in the tissues before and after GC treatment, although transcription  
55  
56  
57 factor *GLCCI1* is induced by GC. Our work shows that *GLCCI1* expressed in the  
58  
59  
60

1  
2  
3  
4  
5  
6 airways, especially in epithelial cells after ICS treatment, and sequential *in vitro*  
7  
8  
9 experiments have shown that the expression was dependent on the genetic variant  
10  
11 *GLCCI1* by using cultured epithelial cells of the airways. The different amounts of  
12  
13 expression of the *GLCCI1* protein induced the varied clinical features. Our data could  
14  
15 not detect the differences between the *GLCCI1* genotypes and the changes of FEV<sub>1</sub>,  
16  
17 however, there was a noticeable change in the treatment steps. Several factors may  
18  
19 explain this discrepancy; foremost, the medications used during the treatment, with the  
20  
21 exception of CS, such as tiotropium and anti-IgE, accounts for a large percentage in the  
22  
23 treatment step 5 population in this study. Anti-IgE antibody omalizumab treatment  
24  
25 significantly improved lung function when added to ICS maintenance therapy in  
26  
27 Japanese asthmatic patients (22). Similarly, tiotropium produced a clinically meaningful  
28  
29 reduction in the exacerbation rate and an improvement in pulmonary function (23).  
30  
31

32  
33  
34  
35  
36  
37  
38  
39  
40  
41 According to GINA guidelines, estimating asthma severity is based on treatment step,  
42  
43 therefore, variants of *GLCCI1* also apply to the predictor of asthma severity.  
44  
45

46  
47 To determine whether there is a fundamental difference in epithelial transcription factor  
48  
49 productions in asthma, we have established primary cultures of bronchial epithelial cells  
50  
51 from normal subjects and asthmatic subjects with and without variants of *GLCCI1*.  
52  
53  
54  
55 Cultured epithelial cells harboring a *GLCCI1* variant expressed modest *GLCCI1* protein  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 compared to the *wt GLCCII*. As infected bronchial epithelial cells with a *GLCCII*  
7  
8  
9 variant had a reduced apoptosis, it seems plausible that virus-induced injury,  
10  
11 specifically to epithelial cells and leading to an enhanced release of IL33, IL25, and  
12  
13 thymic stromal lymphopoietin (24-26), might drive an acute exacerbation of allergic  
14  
15 asthma *via* activation of ILC2 as type 2 cytokine-producing cells.  
16  
17  
18

19  
20 Several potential limitations should be indicated in this study. We did not examine the  
21  
22 initial responsiveness to ICS and annual changes in FEV1 in this cohort. However, we  
23  
24 assume that FEV1, %predicted is also important as a hallmark of the effects of ICS and  
25  
26 airway remodeling. The number of bronchial epithelial cells obtained from asthmatic  
27  
28 participants was small. The main reason is based on the genetic reason of why the  
29  
30 patients harboring the combination of genetics, such as homozygous of rs37972 and *wt*  
31  
32 of rs37973 or *wt* of rs37972 and homozygous of rs37973, were few.  
33  
34  
35  
36  
37  
38  
39  
40

41  
42 In conclusion, we demonstrate an important role for *GLCCII* TT of rs37972 and GG of  
43  
44 rs37973, which increased treatment steps for bronchial asthma. These genetic  
45  
46 biomarkers might transform disease management, especially if these are upstream  
47  
48 factors in the pathogenetic sequence and closer to the disease origins where stratified  
49  
50 medicine is most effective.

45 **Figure 2.** Concentration-change and time course of GLCCI1 induction by fluticasone.

46  
47 Normal human bronchial epithelial cells were treated at the indicated concentration by  
48  
49 fluticasone, and the lysates were subjected to immunoblotting. A representative  
50  
51 immunoblotting GLCCI1 expression in the normal human bronchial epithelial cells  
52  
53  
54  
55  
56 after 24 h exposure to fluticasone at varying concentrations (left in A) and  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 GAPDH-normalized band intensity quantification for GLCCI1 were shown (right in A).

7  
8  
9 A representative immunoblotting GLCCI1 expression in the normal human bronchial

10  
11 epithelial cells after indicated times at 1  $\mu$ M of fluticasone stimulation (left in B) and

12  
13 GAPDH-normalized band intensity quantification for GLCCI1 were shown (right in B).

14  
15  
16  
17 The basal expression in non-treated cells was set to 1.0. Pooled data, quantitating the

18  
19 immunoblot signals using infrared imaging, and the defining for each antibody is shown.

20  
21  
22  
23 Densitometry was significantly increased when cells were cultured at 1 $\mu$ M and 1mM of

24  
25  
26 fluticasone concentration for 24 h compared to those without fluticasone. Also,

27  
28  
29 densitometry showed no significant differences when cells were cultured in the presence

30  
31  
32 of fluticasone within 12 h. The whiskers indicate the standard errors of the mean. \* $P$  <

33  
34  
35 0.05 compared with the means calculated for the no-treatment expression.

36  
37  
38  
39  
40 **Figure 3.** Effects of glucocorticoid on GLCCI1 expression in cultured human bronchial

41  
42 epithelial cells. Epithelial cells were treated without corticosteroid (A), with 1  $\mu$ M

43  
44 fluticasone (B), or with budesonide (C) for 24 h to examine the GLCCI1 expression.

45  
46  
47 Using immunoblotting, cells were harvested, and the cell lysates were then analyzed in

48  
49  
50 immunoblots probes with antibodies directed against GLCCI1 and GAPDH.

51  
52  
53  
54  
55 Representative immunoblotting (left), which was repeated five times, showed

1  
2  
3  
4  
5  
6 equivalent results, and GAPDH-normalized band intensity quantification (right) for  
7  
8  
9 GLCCI1 expression in the epithelial cells after no-exposure (A), exposure to fluticasone  
10  
11 (B), and to budesonide (C). The basal expression in the cells obtained from normal  
12  
13 healthy control was 1.0. Pooled data, quantitating the immunoblot signals using infrared  
14  
15 imaging, and the defining for each antibody is shown. Densitometry showed no  
16  
17  
18 significant differences between the four groups without stimulation, however,  
19  
20 densitometry was significantly decreased in rs37972 and rs37973 compared to healthy  
21  
22 controls when bronchial epithelial cells were cultured in the presence of fluticasone or  
23  
24 budesonide. The whiskers indicate the standard errors of the mean. \* $P < 0.05$  compared  
25  
26 with the means of the normal control expression.

Table 1 Patients characteristics according to the rs37972 genotype GLCCI1

rs37972 genotype	CC (n=132)	CT (n=172)	TT (n=86)	<i>P</i> Value
Age, yr	58.2±1.5	58.1±1.2	56.1±1.9	NS
Sex, n (%)	55 men (42)	75 men (44)	34 men (40)	NS
Eosinophil count / $\mu$ L	309.4±30.5	314.0±19.7	265.1±28.6	NS
IgE level, IU/mL	412.1±58.0	435.2±77.9	565.4±233.2	NS
pulmonary function				
FVC, L	3.0±0.1	2.9±0.1	2.9±0.1	NS
%FVC	97.4±3.0	101.1±2.7	98.7±3.5	NS
FEV1, L	2.2±0.1	2.1±0.1	2.2±0.1	NS
%FEV1	95.1±2.6	96.0±2.4	96.0±3.3	NS

Data are expressed as the mean  $\pm$  standard error of the mean. FVC, forced vital capacity  
FEV1, forced expiratory flow volume in one second, NS, not significant among the  
three groups

Table 2 Patients characteristics according to the rs37973 genotype GLCCI1

rs37973 genotype	AA (n=122)	AG (n=184)	GG (n=92)	<i>P</i> Value
Age, yr	58.7±1.6	58.1±1.2	55.9±1.8	NS
Sex, n (%)	48 men (40)	90 men (49)	37 men (40)	NS
Eosinophil count / $\mu$ L	323.2±32.8	302.5±18.8	321.3±27.4	NS
IgE level, IU/mL	407.5±58.0	439.4±74.9	562.2±221.2	NS
pulmonary function				
FVC	3.0±0.1	2.9±0.1	2.9±0.1	NS
%FVC	99.2±3.2	98.0±2.3	99.6±3.4	NS
FEV1	2.2±0.1	2.1±0.1	2.2±0.1	NS
%FEV1	95.6±2.8	94.3±2.4	96.9±3.1	NS

Data are expressed as the mean  $\pm$  standard error of the mean. FVC, forced vital capacity  
FEV1, forced expiratory flow volume in one second. NS, not significant among the  
three groups
